

(1) Consider the function $f(x) = (x + 1)^2 \ln(x + 1)$. Then:

- (a) draw the graph of the function, obtaining firstly its domain, the intervals where $f(x)$ increases and decreases, its global extrema (if they exist), asymptotes and range.
- (b) consider the new function $f_1(x) = f(x)$ (only defined on the interval where $f(x)$ is increasing). Find the domain, the range and the intervals of concavity/convexity of $f_1^{-1}(x)$. Sketch the graph of this function.

Hint 1: Use that the function f_1 is convex to find the concavity/convexity of $f_1^{-1}(x)$.

Hint 2: Don't try to calculate the analytic expression of $f_1^{-1}(x)$.

Part (a) 0.6 points; Part (b) 0.4 points.

a) The domain of the function is $\{x : x + 1 > 0\} = (-1, \infty)$.

On the other hand, since $f'(x) = 2(x + 1) \ln(x + 1) + x + 1 = (x + 1)(2 \ln(x + 1) + 1)$,

we know that f is decreasing in $(-1, -1 + e^{-1/2}]$ and increasing in $[-1 + e^{-1/2}, \infty)$, so

$1 + 2 \ln(x + 1) = 0 \iff \ln(x + 1) = -\frac{1}{2} \iff x = -1 + e^{-1/2}$ and since the logarithm is an increasing function, then we have

$1 + 2 \ln(x + 1) < 0$ if $x < -1 + e^{-1/2}$ (or, in other words, $f'(x) < 0$ in the first interval); and

$1 + 2 \ln(x + 1) > 0$ if $x > -1 + e^{-1/2}$ (or, $f'(x) > 0$ in the second interval).

Regarding asymptotes, because the function is continuous in its domain we can only look for a vertical asymptote at -1^+ :

$\lim_{x \rightarrow -1^+} f(x) = \lim_{x \rightarrow -1^+} \frac{\ln(x + 1)}{1/(x + 1)^2} = \lim_{x \rightarrow -1^+} \frac{1/(x + 1)}{-2/(x + 1)^3} = 0$; so the function doesn't have a vertical asymptote. Now, we study the behaviour of the function at ∞ :

$\lim_{x \rightarrow \infty} f(x) = \infty = \lim_{x \rightarrow \infty} \frac{f(x)}{x}$; this means that there aren't any horizontal or oblique asymptotes.

Then, the function has a global minimum at $x = -1 + e^{-1/2}$, whose value is:

$$f(-1 + e^{-1/2}) = e^{-1} \ln(e^{-1/2}) = -\frac{1}{2} e^{-1}.$$

and the range of the function is: $[-\frac{1}{2} e^{-1}, \infty)$.

To conclude, the graph of f is approximately like this:

b) We have defined $f = f_1 : [-1 + e^{-1/2}, \infty) \rightarrow [-\frac{1}{2} e^{-1}, \infty)$, so, it is an increasing bijective function. Then, $f_1^{-1} : [-\frac{1}{2} e^{-1}, \infty) \rightarrow [-1 + e^{-1/2}, \infty)$ is also increasing and bijective.

On the other hand, f_1 is convex and increasing, we can deduce that $f_1^{-1}(x)$ is concave, using the symmetry of the inverse function with respect to the first bisector line.

We conclude that the graph of f_1^{-1} is represented approximately like this:

(2) Let $y = f(x)$ be the function defined implicitly by the equation

$$-8x^2 + y^2 + y^6 = 2,$$

in a neighborhood of the point $x = 0, y = 1$. Then:

- (a) find the tangent line of $f(x)$ at $x = 0$, and prove that $f(x)$ is convex near the point.
 (b) sketch the graph of the function around $x = 0$ and calculate approximately the area of the region bounded by the graph of $f(x)$, the x -axis, and the vertical lines $x = -\delta, x = \delta$, for a small $\delta > 0$.
 Is the approximation greater or smaller than the real area?

Hint for (b): If you didn't find required tangent line, consider instead $y = 1 + mx$.

1 point

a) Firstly, we have to calculate the first and second order implicit derivatives of the equation.

First derivative:

$$-16x + 2yy' + 6y^5y' = 8x + (2y + 6y^5)y' = 0$$

then, we evaluate this at $x = 0, y(0) = 1$ to obtain $y'(0) = f'(0) = 0$.

Second derivative:

$$-16 + (2y' + 30y^4y')y' + (2y + 6y^5)y'' = 0$$

and we evaluate at $y(0) = 1, y'(0) = 0$ to deduce that $y''(0) = f''(0) = 2$

Hence, the equation of the tangent line is:

$$y - 1 = 0(x - 0), \text{ or, } y = 1.$$

Obviously, the implicit function is locally convex since, $f''(0) > 0$.

b) Since the graph of f will be above the tangent line $y = 1$, a sketch of this in a neighbourhood of the point $x = 0$, is approximately as follows, taking $\delta = 0, 1$:

Furthermore, because the function is positive near the point $x = 0$, the area will be the integral $\int_{-\delta}^{\delta} f(x)dx$, where we approximately obtain the same result if we exchange $f(x)$ with the tangent line $y = 1$. This means, $\int_{-\delta}^{\delta} f(x) \approx \int_{-\delta}^{\delta} 1.dx = 2\delta$.

Since the function is convex, its graph is underneath the tangent line and the approximate integral is smaller.

Note: If you use the tangent line $y = 1 + mx$, the result is equal because, the area of a rectangle whose base is 2δ and height 1, is exactly the same as the area of a trapezium with the same base and average height 1.

(3) Let $C'(x) = 0.14x + 3$ and $I'(x) = -0.26x + 103$ be the marginal cost and revenue functions of a monopolistic firm, with $x \geq 0$ being the number of produced units of a certain kind of goods. Then:

- (a) find the production that maximizes the profit. For this level of production, For this level of production, the additional **approximate** profit of producing one more or less unit will it be positive or negative?
- (b) knowing that the cost of producing 10 units is 44 monetary units, find the production that minimizes the average cost. For this level of production, what's the additional **approximate** profit of producing one more unit?

Part (a) 0.4 points; Part (b) 0.6 points.

a) Firstly, we have to calculate the first and second derivative of B :

$$B'(x) = I'(x) - C'(x) = -0.26x + 103 - (0.14x + 3) = -0.4x + 100; B''(x) = -0.4 < 0$$

so we notice that B has only one critical point at $x = \frac{100}{0,4} = 250$ and since B is a concave function, then the critical point is a global maximizer.

With this level of production, the additional profit of producing one more or one less unit will be negative, but close to 0, since $x = 250$ is the global maximizer of $B(x)$.

b) The cost function is $C(x) = 0,07x^2 + 3x + C_0$.

$$\text{Since } C(10) = 0,07 \cdot 10^2 + 3 \cdot 10 + C_0 = 44 \implies C_0 = 7,$$

$$\text{the average cost function is } C_m(x) = \frac{C(x)}{x} = \frac{7}{x} + 3 + 0,07x.$$

If we calculate its first and second order derivative function:

$$C'_m(x) = \frac{-7}{x^2} + 0,07; C''_m(x) = \frac{14}{x^3} > 0$$

we can see that $x = \sqrt{\frac{7}{0,07}} = 10$ is the only critical point and because $C_m(x)$ is a convex function, that critical point is the only global minimizer.

Therefore, the level of production that minimizes the average cost is $x = 10$.

For this level of production, the additional profit of producing an extra unit will be approximately 96 m.u., since:

$$B(11) - B(10) \approx B'(10) = -4 + 100 = 96$$

(4) Given the set $A = \{(x, y) \in \mathbb{R}^2 : x^2 \leq y \leq 3 - 2|x|\}$. Then:

- (a) draw the set A and find, if they exist, the maximal/minimal elements, the maximum and the minimum of A .
 (b) calculate the area enclosed by the set A . What's the area enclosed by

$$B = \{(x, y) \in \mathbb{R}^2 : x^2 + 1 \leq y \leq 4 - 2|x|\}?$$

Hint for (a): Pareto order is defined by: $(x_0, y_0) \leq_P (x_1, y_1) \iff x_0 \leq x_1$ and $y_0 \leq y_1$.

Hint for (b): What is the relation between the sets A and B ?

Part (a) 0.6 points; Part (b) 0.4 points.

- a) Since the set A is symmetric with respect to the y -axis, we can just focus our attention on $x \geq 0$. For those values, $(x, y) \in A$ if

$$f(x) = x^2 \leq y \leq 3 - 2x = g(x).$$

The graphs of both functions $y = x^2, y = 3 - 2x$ intercept at $x = 1$.

Therefore, the sketch of A will be approximately:

Since, $g(x)$ is decreasing on $[0, 1]$ and $f(x)$ is also decreasing on $[-1, 0]$,

Pareto's order describes the special points in the set as:

$maximum(A)$ doesn't exist, $\{maximals(A)\} = \{(x, 3 - 2x) : 0 \leq x \leq 1\}$.

$minimum(A)$ doesn't exist, $\{minimals(A)\} = \{(x, x^2) : -1 \leq x \leq 0\}$.

- b) As we have mention before, the area is going to be twice the area of the set on the right to the y -axis. So,

$$\begin{aligned} A &= 2 \int_0^1 (g(x) - f(x)) dx = 2 \int_0^1 (3 - 2x - x^2) dx = 2 \left[3x - x^2 - \frac{1}{3}x^3 \right]_0^1 = \\ &= 2 \left(3 - 1 - \frac{1}{3} \right) = \frac{10}{3} \text{ square units.} \end{aligned}$$

On the other hand, B is just one unit vertical translation upwards of the set A , So the area of B is the same as that of A .
