

Technological adoption: Catching-up to the frontier

Felix Wellschmied

Universidad Carlos III de Madrid

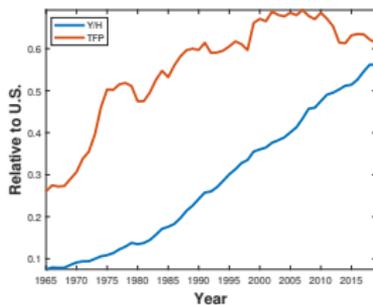

Growth Theory

Introduction

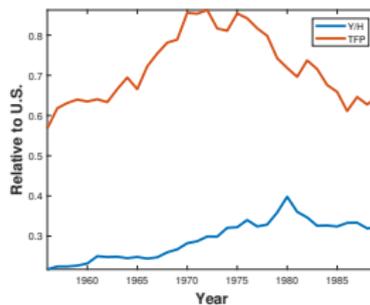

- We have seen a model that describes the discovery of entirely new ideas by researchers at the frontier.
- We have seen in the case of Korea, that much more rapid technological growth is possible for a country far away from the frontier.
- However, even in the case of Korea, we have seen that it did not fully converge.
- It is reasonable to think that implementing an already existing idea is simpler than discovering it anew.
- However, given large TFP differences in the cross-section, convergence taking decades, and convergence often not being complete, implementation cannot be frictionless.

TFP growth

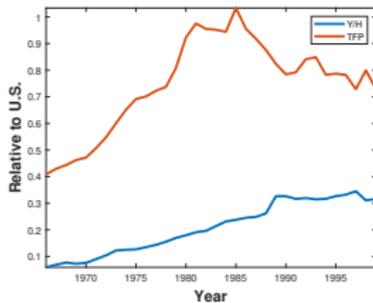

(a) Korea

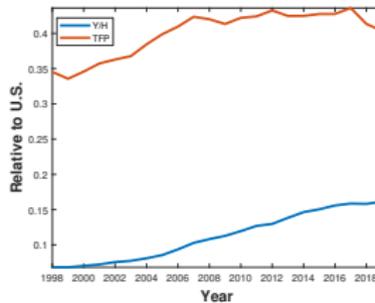

(b) Brazil

(c) Botswana

(d) China

A model of technological adoption

We use the insights from the Romer model and assume output uses differentiated capital goods:

$$Y(t) = L(t)^{1-\alpha} \int_0^{h(t)} x_j(t)^\alpha dj. \quad (1)$$

Here, $h(t)$ is the measure of capital goods that the country knows how to use in period t . This may be different from the technological frontier $A(t)$. For example, the U.S. may know how to produce mRNA vaccines but China does not.

Rewriting the production function

As in the Romer model, each unit of capital goods needs to be produced using a unit of the aggregate available aggregate capital stock:

$$\int_0^{h(t)} x_j(t) dj = K(t). \quad (2)$$

Moreover, each unit is used in the same proportion:

$$x_j(t) = x(t) = \frac{K(t)}{h(t)}. \quad (3)$$

Substituting into the production function:

$$Y(t) = L(t)^{1-\alpha} h(t) x(t)^\alpha \quad (4)$$

$$Y(t) = (L(t)h(t))^{1-\alpha} K(t)^\alpha. \quad (5)$$

Household income

There is no research sector, instead all labor works in the production sector. The wage and the rental price of capital are

$$w(t) = \frac{\partial Y(t)}{\partial L(t)} = 1 - \alpha \frac{Y(t)}{L(t)} \quad (6)$$

$$r(t) = \frac{\partial Y(t)}{\partial K(t)} = \alpha \frac{Y(t)}{K(t)}. \quad (7)$$

Hence, we have again for household income that

$$\tilde{Y}(t) = w(t)L(t) + r(t)K(t) = Y(t). \quad (8)$$

Accumulation of factors of production

The household sector, as before, accumulates the aggregate capital stock :

$$\dot{K}(t) = sY(t) - \delta K(t), \quad (9)$$

The population grows at rate n :

$$\dot{L}(t) = nL(t). \quad (10)$$

Skill accumulation

Key to the model is the accumulation of the skill level h . Skills evolve over time according to

$$\dot{h}(t) = \mu \exp(\psi u) A(t)^\gamma h(t)^{1-\gamma} \quad (11)$$

- As in the model of human capital accumulation, u measures the time people spend learning new skills. This may be explicit research activity or learning-by-doing.
- The current level of skills makes it easier to learn new skills, i.e., $\gamma < 1$.
- A further developed technological frontier makes it easier to learn new skills, i.e., $\gamma > 0$.

Rewrite in growth rates

$$\frac{\dot{h}(t)}{h(t)} = \mu \exp(\psi u) \left(\frac{A(t)}{h(t)} \right)^\gamma \quad (12)$$

The speed of adoption depends on the distance to the technological frontier. When that distance is large, $\frac{A}{h}$ is large, skill accumulation growth is fast. I.e., it is easier to copy technologies that are already in use for a long time. Finally, we assume that the frontier grows according to

$$\frac{\dot{A}(t)}{A(t)} = g. \quad (13)$$

Steady state

Given the production function, we know already that the capital-to-output ratio solves for:

$$z^* = \left(\frac{K(t)}{Y(t)} \right)^* = \frac{s}{n + g_h(t) + \delta}, \quad (14)$$

which has a steady state if $g_h(t) = g_h$, a constant, in steady state. Hence, in steady state, output per worker is

$$\left(\frac{Y(t)}{L(t)} \right)^* = \left(\frac{s}{n + g_h(t) + \delta} \right)^{\frac{\alpha}{1-\alpha}} h(t). \quad (15)$$

Next, we derive g_h and $h(t)$.

For the growth rate of skills

$$\frac{\dot{h}(t)}{h(t)} = \mu \exp(\psi u) \left(\frac{A(t)}{h(t)} \right)^\gamma \quad (16)$$

to be constant, we directly see that $\frac{A(t)}{h(t)}$ needs to be constant, i.e., $g_h = g$.

Output per worker growth in steady state

Going back to the equation for output per worker:

$$\left(\frac{Y(t)}{L(t)}\right)^* = \left(\frac{s}{n + g_h(t) + \delta}\right)^{\frac{\alpha}{1-\alpha}} h(t) \quad (17)$$

Here, $h(t)$ is the only time-varying variable. We know its steady state growth rate is g and, hence, we know that output per worker also grows at rate g in steady state.

The distance to the frontier in steady state

$$\frac{\dot{h}(t)}{h(t)} = \mu \exp(\psi u) \left(\frac{A(t)}{h(t)} \right)^\gamma \quad (18)$$

$$g = \mu \exp(\psi u) \left(\frac{A(t)}{h(t)} \right)^\gamma \quad (19)$$

$$\frac{h(t)}{A(t)} = \left(\frac{\mu \exp(\psi u)}{g} \right)^{\frac{1}{\gamma}}. \quad (20)$$

An environment more conducive to skill accumulation pushes the economy closer to the technological frontier. However, the economy can be permanently below the technological frontier.

Obtaining $h(t)$

To obtain the level of skills, we need to solve the differential equation of skill accumulation:

$$\dot{h}(t) = \mu \exp(\psi u) A(t)^\gamma h(t)^{1-\gamma}, \quad (21)$$

One can show that this solves for

$$h(t) = \left(h(0)^\gamma + \frac{1}{g} \mu \exp(\psi u) A(0)^\gamma [\exp(\gamma g t) - 1] \right)^{\frac{1}{\gamma}} \quad (22)$$

The level of $h(t)$

$$h(t) = \left(h(0)^\gamma + \frac{1}{g} \mu \exp(\psi u) A(0)^\gamma [\exp(\gamma g t) - 1] \right)^{\frac{1}{\gamma}} \quad (23)$$

- A higher initial skill level increases skills today.
- A higher initial level of the of technology in the rest of the world increases skills.
- A more conducive skill accumulation environment increases the skill level.

Output per worker in steady state

$$\left(\frac{Y(t)}{L(t)}\right)^* = \left(\frac{s}{n + g_h + \delta}\right)^{\frac{\alpha}{1-\alpha}} \left(h(0)^\gamma + \frac{1}{g}\mu \exp(\psi u) A(0)^\gamma [\exp(\gamma g t) - 1]\right)^{\frac{1}{\gamma}} \quad (24)$$

- Higher capital to output ratio leads to higher output per worker. Hence, for a developing economy, population growth decreases output per worker unambiguously as it no longer affects $A(t)$.
- The model provides a reason why skills lead to higher output per worker. Skills do not make workers more productive in the abstract, they make them more productive by allowing them to use more capital goods.
- Pushing out the technological frontier benefits all countries as they can copy those new ideas over time.

Skill accumulation outside the steady state

Recall that skills evolve over time according to

$$\dot{h}(t) = \mu \exp(\psi u) A^\gamma h(t)^{1-\gamma}, \quad (25)$$

where, for simplicity, I assume that $A(t)$ is a constant. That is, we study convergence to a higher but fixed technological frontier. Now define

$$v(t) = h(t)^\gamma \quad (26)$$

with

$$\dot{v}(t) = \dot{h}(t) \gamma h(t)^{\gamma-1} \quad (27)$$

Substituting yields

$$\dot{v}(t) = \gamma \mu \exp(\psi u) A^\gamma. \quad (28)$$

$$\dot{v}(t) = \gamma \mu \exp(\psi u) A^\gamma \quad (29)$$

with solution

$$v(t) = \gamma \mu \exp(\psi u) A^\gamma t + v(0) \quad (30)$$

Substituting again $v(t) = h(t)^\gamma$ yields

$$h(t) = [\gamma \mu \exp(\psi u) A^\gamma t + h(0)^\gamma]^{\frac{1}{\gamma}}. \quad (31)$$

Hence, the growth rate of $h(t)$ is given by

$$\frac{\dot{h}(t)}{h(t)} = \frac{1}{\gamma t + \frac{1}{\mu \exp(\psi u)} \left(\frac{h(0)}{A}\right)^\gamma}. \quad (32)$$

- The growth rate is higher the further the initial skill level is away from the technological frontier.
- The growth rate slows down over time, i.e., technological catch-up should occur in a concave fashion.
- For any $h(0)$, A , increasing μ , ψ , or u increases $\frac{\dot{h}(t)}{h(t)}$.

Transition dynamics for output per worker

As before, let us write output as a function of the capital to output ratio

$$Y(t) = h(t)L(t) \left(\frac{K(t)}{Y(t)} \right)^{\frac{\alpha}{1-\alpha}} \quad (33)$$

$$y(t) = h(t) \left(\frac{K(t)}{Y(t)} \right)^{\frac{\alpha}{1-\alpha}} \quad (34)$$

$$y(t) = h(t)\tilde{k}(t)^\alpha \quad (35)$$

$$\frac{\dot{y}(t)}{y(t)} = \frac{\dot{h}(t)}{h(t)} + \alpha \frac{\dot{\tilde{k}}(t)}{\tilde{k}(t)} \quad (36)$$

with

$$\frac{\dot{\tilde{k}}(t)}{\tilde{k}(t)} = \frac{\dot{K}(t)}{K(t)} - \frac{\dot{h}(t)}{h(t)} - n \quad (37)$$

$$\frac{\dot{\tilde{k}}(t)}{\tilde{k}(t)} = s\tilde{k}(t)^{\alpha-1} - \delta - \frac{\dot{h}(t)}{h(t)} - n \quad (38)$$

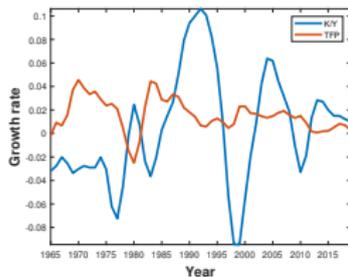

Transition dynamics for output per worker II

$$\frac{\dot{y}(t)}{y(t)} = \frac{\dot{h}(t)}{h(t)} + \alpha \left[s\tilde{k}(t)^{\alpha-1} - \left(n + \delta + \frac{\dot{h}(t)}{h(t)} \right) \right] \quad (39)$$

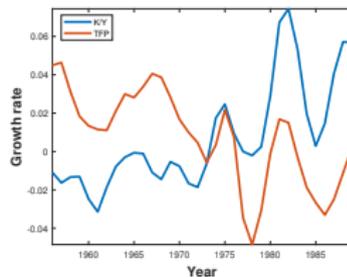

Similar to the Romer model, a temporary increase in $\frac{\dot{h}(t)}{h(t)}$ increases the growth rate of $y(t)$ but it increases it initially by less than the increase in $\frac{\dot{h}(t)}{h(t)}$ because the capital to output ratio declines initially.

Knowledge spillover and trade

Knowledge spillover and trade

So far, we assume that the technological frontier is available to all countries. However, there are good reasons to believe that trade is important for new technologies becoming available to countries:

- A famous example is China severely restricting trade in the 14th century which coincides with its downfall as technological leader.
- The trade embargo on modern Iran coincides with Iran losing in terms of output per worker.
- FDI into China was an important source of technological adoption.
- Patenting may assure that recent inventions can only be bought from abroad.

The data suggests that a link exists II

Changing the production function

Assume h capital goods are produced at home and m are imported:

$$Y(t) = L(t)^{1-\alpha} \int_0^{h(t)+m} x_j(t)^\alpha dj. \quad (40)$$

A country produces $z(t)$ units of each home-based capital good and, hence,:

$$z(t)h(t) = K(t). \quad (41)$$

Again, a country wishes to use the same amount of each capital good, both home-produced and foreign. Let this be $x(t) < z(t)$. Thus, the country keeps only $x(t)h(t)$ of these goods and buys $x(t)m$ of the imported goods. Hence, balanced trade implies:

$$x(t)m = K(t) - x(t)h(t) \quad (42)$$

$$K(t) = x(t)[m + h(t)]. \quad (43)$$

Rewriting the production function

Equal input usage implies

$$Y(t) = L(t)^{1-\alpha} \int_0^{h(t)+m} x_j(t)^\alpha dj \quad (44)$$

$$Y(t) = L(t)^{1-\alpha} (h(t) + m)x(t)^\alpha. \quad (45)$$

Using the trade balance:

$$Y(t) = L(t)^{1-\alpha} (h(t) + m) \left(\frac{K(t)}{m + h(t)} \right)^\alpha \quad (46)$$

$$Y(t) = ([m + h(t)]L(t))^{1-\alpha} K(t)^\alpha \quad (47)$$

$$Y(t) = K(t)^\alpha (h(t)L(t))^{1-\alpha} \left[1 + \frac{m}{h(t)} \right]^{1-\alpha} \quad (48)$$

Steady state

Define $N(t) = h(t) + m(t)$ and consider again the growth rate of the capital-to-output ratio, and the capital accumulation equation:

$$z(t) = \frac{K(t)^{1-\alpha}}{(N(t)L(t))^{1-\alpha}} \quad \frac{\dot{z}(t)}{z(t)} = 1 - \alpha \frac{\dot{K}(t)}{K(t)} - 1 - \alpha \left(n + \frac{\dot{N}(t)}{N(t)} \right) \quad (49)$$

$$\frac{\dot{z}(t)}{z(t)} = \frac{s}{z(t)} - \delta. \quad (50)$$

Combining the equations and assuming that a steady state exists:

$$n + \frac{\dot{N}(t)}{N(t)} = \frac{s}{z^*} - \delta \quad (51)$$

$$z^* = \frac{s}{n + \frac{\dot{N}(t)}{N(t)} + \delta}, \quad (52)$$

which is constant if $\frac{\dot{N}(t)}{N(t)} = g_N(t)$ is constant. One can show, that, in steady state, $g_N(t) = g$, i.e., a constant.

Output per worker in steady state

From the production function:

$$Y(t)^{1-\alpha} = \left(\frac{K(t)}{Y(t)} \right)^\alpha ([h(t) + m]L(t))^{1-\alpha} \quad (53)$$

$$Y(t) = \left(\frac{K(t)}{Y(t)} \right)^{\frac{\alpha}{1-\alpha}} [h(t) + m]L(t) \quad (54)$$

$$(55)$$

In steady state:

$$Y(t)^* = \left(\frac{s}{n + g + \delta} \right)^{\frac{\alpha}{1-\alpha}} [h(t) + m]L(t) \quad (56)$$

$$y(t)^* = \left(\frac{s}{n + g + \delta} \right)^{\frac{\alpha}{1-\alpha}} [h(t) + m] \quad (57)$$

The steady state II

$$y(t)^* = \left(\frac{s}{n + g + \delta} \right)^{\frac{\alpha}{1-\alpha}} [h(t) + m(t)] \quad (58)$$

(59)

Income per worker is increasing in the number of imported varieties of capital goods. Trade makes us richer as it allows us access to capital goods currently not produced in our country.

$$y(t)^* = \left(\frac{s}{n + g + \delta} \right)^{\frac{\alpha}{1-\alpha}} [h(t) + m] \quad (60)$$

- Trade can be a substitute for skills. By selling “unsophisticated” capital goods, the country can gain access to more advanced capital goods. Note, the implications would be somewhat different in a Schumpeterian model.
- China is a good example. By foreign countries bringing their technologies with them and using an uneducated Chinese workforce, output was able to grow at tremendous rates.

Back to our three big questions

- ① Why are we so rich and they so poor?
 - Different saving rates, population growth rates, technologies for idea adoption, skill levels, and trade openness.
- ② Why are there growth miracles?
 - Rapid accumulation of physical capital or ideas.
- ③ What are the engines of long run economic growth?
 - Skill accumulation.

LÓPEZ, M. C. AND B. DE BLAS PÉREZ (2018): “Faraway, so close!, technology diffusion and firm heterogeneity in the medium term cycle of advanced economies,” *Documentos de trabajo del Banco de España*, 1–64.
